

Welcome to the  
2019 Hampshire College  
Summer Studies in Mathematics  
INTERESTING TEST

Name:

Sponsor:

School:

[This is a link to the article College Admissions and the Stability of Marriage, the basis for IT's 2nd problem.](#)

You should try to limit the time you spend on the IT to 7 or 8 hours, indicating as afterthoughts later ideas (which can be sent separately). Send IT in just before you run out of ideas to try. We don't want this application to become a career or to interfere with other studies.

Enjoy the IT; expect much of IT to be unfamiliar, but don't expect to complete all of IT. Email me if you suspect that there is an error on the IT or if a problem remains incomprehensible; do not suffer in silence. Please send questions about the IT to: [dckNS@hampshire.edu](mailto:dckNS@hampshire.edu) with the subject line: "[your name]'s IT Question [date]."

Let us know if you can't finish within 17 days. This is not a rigid deadline--just let us know that your candidacy is still active with a note to [sgoff@hampshire.edu](mailto:sgoff@hampshire.edu) with the subject line: "[your name]'s IT update [date]."

Let your reasoning and computations show. Use the provided spaces, but feel free to use the backs of pages and additional paper as needed. Feel obligated to use additional space if the alternative is tiny-fonted cramped writing. Leave space between lines. We do not need to see your scratch work, but you're welcome to tell us about efforts that didn't work out. Revise and neaten your work. The harder it is to decipher your writing or to find strands of logic or complete sentences, the less inclined we'll be to spend 6 weeks doing it with you this summer. Spend more time doing your work than digitizing it. Feel free to add generalizations, speculations, and questions.

One reason you've applied to HCSSiM is that you enjoy sharing mathematics—but please do not discuss these questions. Instead, encourage those with whom you'd like to share IT ideas to apply to the Summer Studies promptly. As you know: Applying is fast, free, fun, obligationless, and doable on line even while (especially if) other options are being explored; not applying unnecessarily closes doors, means not seeing the Interesting Test, and may cause drowsiness and boredom.

We're not testing your Internet search skills. (In fact, we are not very concerned with how much you know—there's no need to flaunt prior knowledge.) Do not use the Internet for IT. You are obliged to tell us if you have encountered in the past or stumble upon relevant information online.

Paper submissions are still fine. Send well-labeled things to:

David C. Kelly or Susan Goff  
HCSSiM, Box NS  
Hampshire College  
893 West St.  
Amherst, MA 01002-3359

Important advice: When you send things electronically the email's subject line and the name of each and every attachment should identify you, an approximate date, and hint about the content. Please combine things into as few pdfs (e.g., one) as possible when you send your IT work to [sgoff@hampshire.edu](mailto:sgoff@hampshire.edu) and use the subject line: "[your name]'s 2019 IT work, [date]."

Give us more feedback, please, when you have completed your work on the 2019 HCSSiM Interesting Test:

How and how long did you work on the IT?

Which, if any, of the problems had you considered before?

Which, if any, did you particularly enjoy?

Particularly not enjoy?

Other comments:

Thanks.

FIBONACCI SQUARES  $f_1 = f_2 = 1$ , and  $f_n = f_{n-1} + f_{n-2}$  for  $n > 2$ .

$$\sum_{k=1}^n f_k^2 = 1 + 1 + 4 + 9 + 16 + \cdots + f_n^2 = \underline{\hspace{2cm}} .$$

$f_{n-1}f_{n+1} - f_n^2 = \underline{\hspace{2cm}} . \qquad f_{n-2}f_{n+2} - f_n^2 = \underline{\hspace{2cm}} .$

A square with side  $f_n$  is partitioned into triangles and trapezoids which, it seems, can be rearranged to form a rectangle or an octagon with different areas.

In terms of the  $f_k$ s, what are dimensions of the triangles and trapezoids that create the paradox?  
Please explain the paradox; and specify the property (or properties) of Fibonacci numbers that you think are relevant to creating it.

## STABLE MARRIAGES

Based on *College Admissions and the Stability of Marriage* by L. S. Shapley and D. Gale. (Link on IT cover page.)

Explain why the Gale-Shapley algorithm with  $n$  men and  $n$  women terminates in at most  $n^2 - 2n + 2$  stages.

Are there preference tables that will cause it to last that long for every  $n$ ?

For the preferences table on p.13, find the man-optimal set of marriages and the woman-optimal set of marriages:

$\alpha \leftrightarrow \_\_\_\_\_\_ , \beta \leftrightarrow \_\_\_\_\_\_ , \gamma \leftrightarrow \_\_\_\_\_\_ , \delta \leftrightarrow \_\_\_\_\_\_ ; \quad A \leftrightarrow \_\_\_\_\_\_ , B \leftrightarrow \_\_\_\_\_\_ , C \leftrightarrow \_\_\_\_\_\_ , D \leftrightarrow \_\_\_\_\_\_ .$

Back to the general case: Show that, when the women do the proposing, the resulting set of marriages is as bad as any stable set of marriages could be for each man.

Not all of the results about marriages generalize to college admissions: In this 3-college 4-student example,  $c_1$  has a 2-student quota while  $c_2$  and  $c_3$  are 1-student colleges. Their rankings (from most to least favored) are:

$c_1 : s_1, s_2, s_3, s_4; \quad c_2 : s_1, s_2, s_3, s_4; \quad c_3 : s_3, s_1, s_2, s_4;$   
 $s_1 : c_3, c_1, c_2; \quad s_2 : c_2, c_1, c_3; \quad s_3 : c_1, c_3, c_2; \quad s_4 : c_1, c_2, c_3.$

Show that when the colleges do the "proposing" (so that, on day 1,  $c_1$  invites  $s_1$  and  $s_2$ ), the resulting assignment of students to colleges is (very) stable. There is, however, another stable arrangement favored by all the colleges.

What do you think about the Gale-Shapley paper?

# TILING WITH TETROMINOES

Too the right, some tetrominoes are playing.  
How many different tetrominoes are there? \_\_\_\_.

A *fault-free* tiling? Can an  $8 \times 8$  grid can be tiled with L-tetrominoes (and reflections thereof) so that every horizontal or vertical line separating the grid into two non-empty pieces cuts through at least one tetromino?  
(What is the difference between an  $8 \times 8$  grid and and an  $8 \times 8$  checkerboard?)

Can an  $8 \times 8$  checkerboard can be tiled with  
15 L-tetrominoes and one  $2 \times 2$  square?

Let  $T(N)$  = the number of ways a  $2 \times N$  grid can be tiled with tetrominoes.

$T(1) = \underline{\hspace{1cm}}$  ,  $T(2) = \underline{\hspace{1cm}}$  ,  $T(3) = \underline{\hspace{1cm}}$  ,  $T(4) = \underline{\hspace{1cm}}$  ,  $T(5) = \underline{\hspace{1cm}}$  ;

and  $T(6) = \underline{\hspace{1cm}}$ . (Hint:  $5.17 \leq T(6) \leq 11$ ).

Can you determine  $T(N)$ ?

(If you want to define  $T(0)$ , feel free to let IT know what you want it to be.)

1																	1
1								2									1

⋮																	

THE TABLE

Before seeing if you can determine without a computer the 17th entry in the 2019th row of this table or the number of times 2019 appears in that row, and before deciding if it would be possible, interesting, or fun to write a computer program to answer those questions, write down some ( $\geq 3, \leq 10$ ) more reasonable questions about the table. Try to answer (or get partial results for) a few of those questions. See if you can formulate a conjecture that you don't now have a proof or counterexample for, but which you might want to investigate further later.
